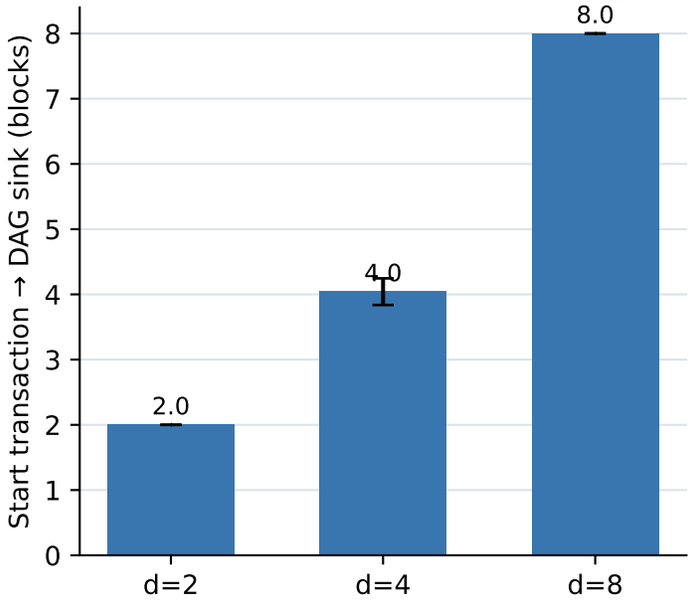
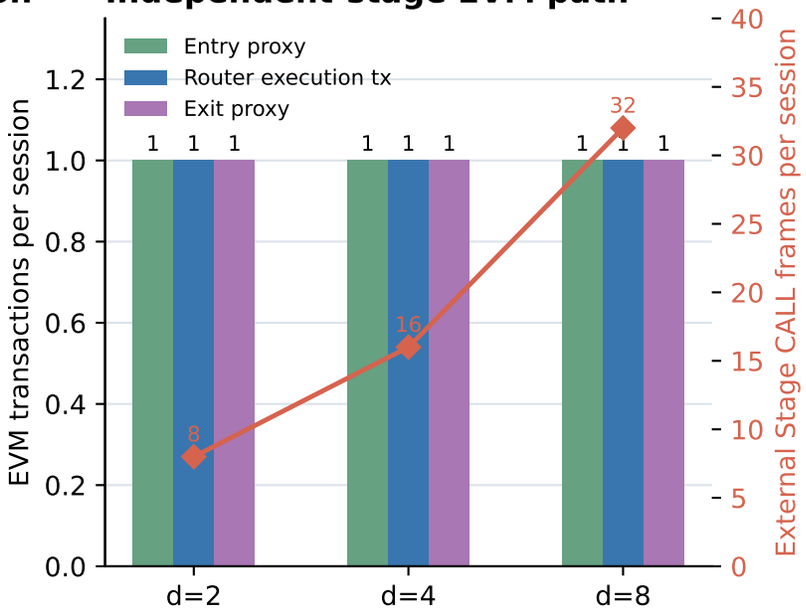
Dependency completion and native execution units

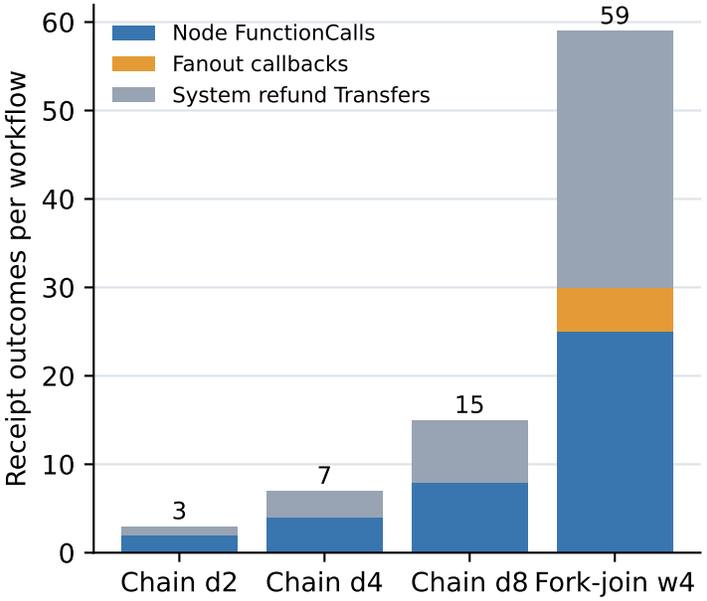
NEAR multi-contract sink completion



Independent-stage EVM path



NEAR outcome-tree classification



Interpretation

The measured NEAR path adds asynchronous contract-call dependencies as d grows.

Each EVM session has one Router execution transaction and θ × node-count external CALLs to independent Stage contracts.

The earlier monolithic EVM runner is retained separately as a fused control.

For the width-4 DAGs, the sink completes at +4 blocks; the full callback/refund tree drains at +6.

Entry and exit bars are local storage-commitment proxies, not bridge proofs or measured migration.

NEAR blocks and EVM transaction counts are separate units; no cross-runtime time ratio is inferred.
